Class13_BillyWegeng_A12340146

```
library(DESeq2)
```

```
counts <- read.csv("airway_scaledcounts.csv", row.names=1)
metadata <- read.csv("airway_metadata.csv")
```

Q1. How many genes are in this dataset?

```
nrow(counts)
```

```
[1] 38694
```

Q2. How many 'control' cell lines do we have?

```
sum(metadata$dex == "control")
```

```
[1] 4
```

```
table(metadata$dex)
```

```
control treated
      4       4
```

I want to compare the control to the treated columns. To do this I will

-Step 1. Identify and extract the "control" columns. -Step 2. Calculate the mean value per gene for all these "control" columns and save as `control.mean`. -Step 3. Do the same for treated -Step 4. Compare the `control.mean` and `treated.mean` values.

Step 1:

```
control.inds <- metadata$dex=="control"
```

```
metadata[control.inds,]
```

```
         id     dex celltype     geo_id
1 SRR1039508 control   N61311 GSM1275862
3 SRR1039512 control  N052611 GSM1275866
5 SRR1039516 control  N080611 GSM1275870
7 SRR1039520 control  N061011 GSM1275874
```

```
control.means <- rowMeans(counts[,control.inds])
head(control.means)
```

```
ENSG00000000003 ENSG00000000005 ENSG00000000419 ENSG00000000457 ENSG00000000460
         900.75            0.00          520.50          339.75           97.25
ENSG00000000938
           0.75
```

```
treated.inds <- metadata$dex=="treated"
treated.means <- rowMeans(counts[,treated.inds])
head(treated.means)
```

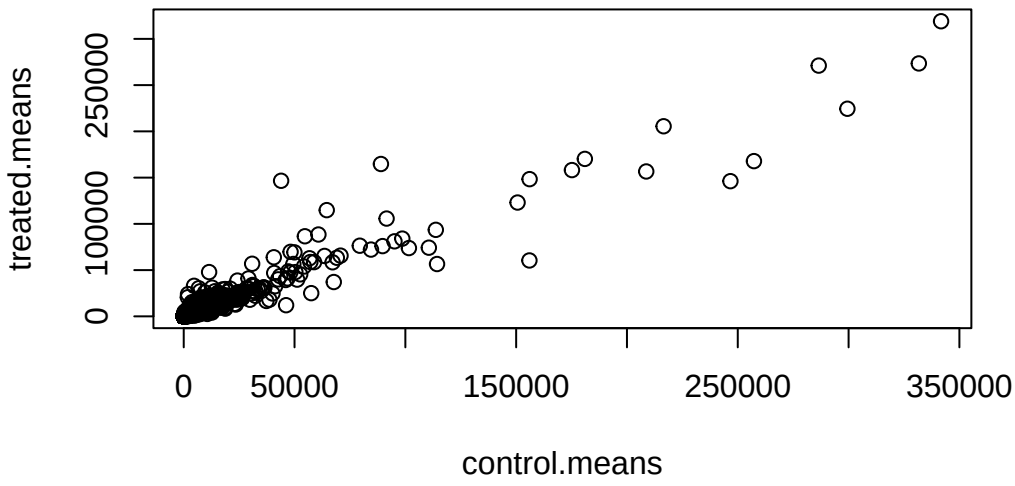
```
ENSG00000000003 ENSG00000000005 ENSG00000000419 ENSG00000000457 ENSG00000000460
         658.00            0.00          546.00          316.50           78.75
ENSG00000000938
           0.00
```

We will combine our meancount data for bookkeeping piurposes.

```
meancounts <- data.frame(control.means, treated.means)
```

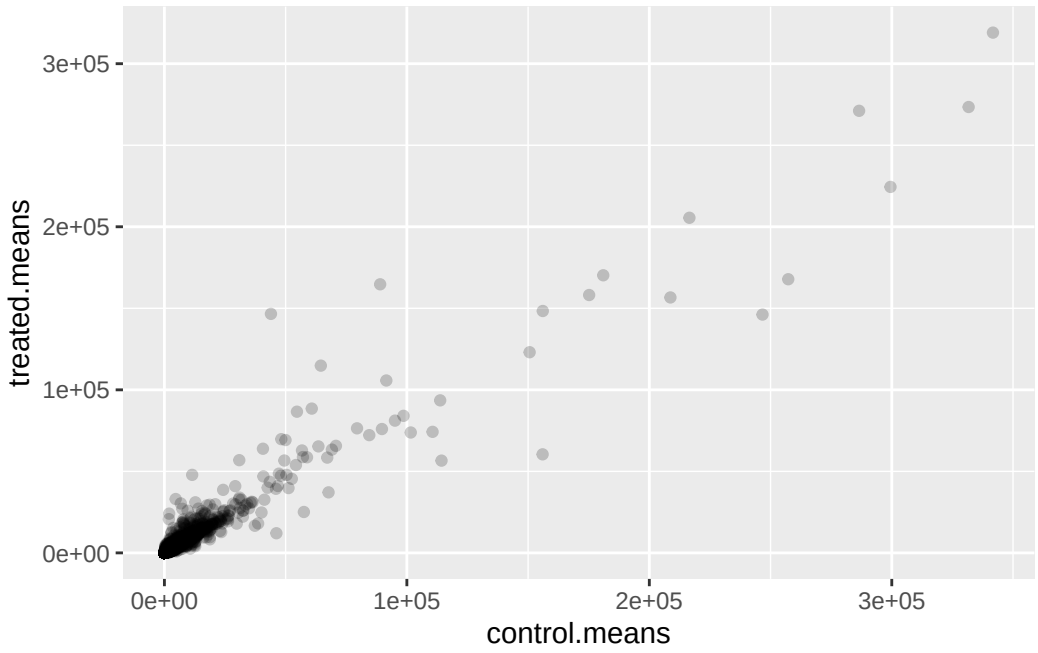
Let's see what these count calues look like.

```
plot(meancounts)
```



```
library(ggplot2)
```

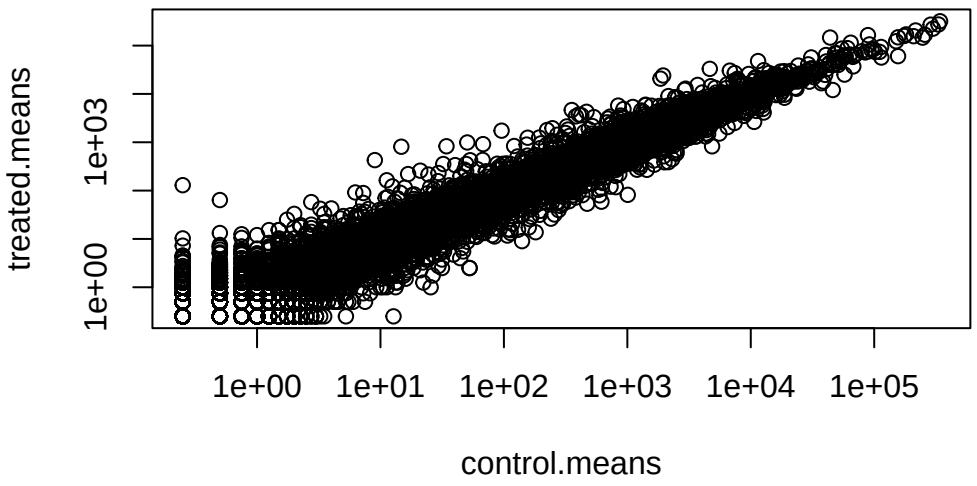
```
ggplot(meancounts) + aes(control.means, treated.means) + geom_point(alpha=0.2)
```



```
plot(meancounts, log="xy")
```

```
Warning in xy.coords(x, y, xlabel, ylabel, log): 15032 x values <= 0 omitted
from logarithmic plot
```

```
Warning in xy.coords(x, y, xlabel, ylabel, log): 15281 y values <= 0 omitted
from logarithmic plot
```



Logs are super useful when we have such skewed data they are also handy when we are msot interested in

```
# Treated / control
log2(10/10)
```

```
[1] 0
```

```
log2(20/10)
```

```
[1] 1
```

```
log2(40/10)
```

```
[1] 2
```

Add log2(Fold-change) values to our wee results table.

```
meancounts$log2fc <- log2(meancounts$treated.means/meancounts$control.means)

head(meancounts)
```

```
                control.means treated.means      log2fc
ENSG00000000003        900.75        658.00 -0.45303916
ENSG00000000005          0.00          0.00         NaN
ENSG00000000419        520.50        546.00  0.06900279
ENSG00000000457        339.75        316.50 -0.10226805
ENSG00000000460         97.25         78.75 -0.30441833
ENSG00000000938          0.75          0.00        -Inf
```

I need to exclude any genes with zero counts as we can't say anything about them anyway from this experiment and it causes me math pain.

```
# What values in the first two cols are zero

to.rm.inds <- rowSums(meancounts[,1:2] == 0) > 0
mycounts <- meancounts[!to.rm.inds, ]
```

```
which( c(TRUE,FALSE,TRUE))
```

```
[1] 1 3
```

Q. How many genes do I have left?

```
nrow(mycounts)
```

```
[1] 21817
```

Q. How many genes are "up regulated" i.e. have a log2(fold-change) greater than +2?

```
sum(mycounts$log2fc > +2)
```

```
[1] 250
```

Q. How many are "down"?

```
sum(mycounts$log2fc < -2)
```

```
[1] 367
```

Running DESeq

Like many bioconductor analysis packges DESeq wants it's input in a very particular way.

```
dds <- DESeqDataSetFromMatrix(countData = counts, colData = metadata, design =~ dex)
```

```
converting counts to integer mode
```

```
Warning in DESeqDataSet(se, design = design, ignoreRank): some variables in
design formula are characters, converting to factors
```

To run DESeq analysis we call the main function form the package called `DESeq(dds)`

```
dds <- DESeq(dds)
```

```
estimating size factors
```

```
estimating dispersions
```

```
gene-wise dispersion estimates
```

```
mean-dispersion relationship
```

```
final dispersion estimates
```

```
fitting model and testing
```

To get the results out of this `dds` object we can use the DESeq `results()` function.

```
res <- results(dds)
head(res)
```

```
